List of Publications

Listed below are the publications that I (co)authored during the Ph.D. project. These are grouped by: the main publications, which are also included in Part IX, papers where I had a supervisory role, and finally, miscellaneous publications.

Main Publications

- [A] S. Willemsen, N. Andersson, S. Serafin, and S. Bilbao, “Real-time control of large-scale modular physical models using the sensel morph,” in *Proceedings of the 16th Sound and Music Computing (SMC) Conference*, 2019, pp. 275–280.
- [B] S. Willemsen, S. Bilbao, N. Andersson, and S. Serafin, “Physical models and real-time control with the sensel morph,” in *Proceedings of the 16th Sound and Music Computing (SMC) Conference*, 2019, pp. 95–96.
- [C] S. Willemsen, S. Bilbao, and S. Serafin, “Real-time implementation of an elasto-plastic friction model applied to stiff strings using finite difference schemes,” in *Proceedings of the 22nd International Conference on Digital Audio Effects (DAFx-19)*, 2019, pp. 40–46.
- [D] S. Willemsen, S. Serafin, S. Bilbao, and M. Ducceschi, “Real-time implementation of a physical model of the tromba marina,” in *Proceedings of the 17th Sound and Music Computing (SMC) Conference*, 2020, pp. 161–168.
- [E] S. Willemsen, R. Paisa, and S. Serafin, “Resurrecting the tromba marina: A bowed virtual reality instrument using haptic feedback and accurate physical modelling,” in *Proceedings of the 17th Sound and Music Computing (SMC) Conference*, 2020, pp. 300–307.
- [F] S. Willemsen, A.-S. Horvath, and M. Nascimben, “Digidrum: A haptic-based virtual reality musical instrument and a case study,” in *Proceedings of the 17th Sound and Music Computing (SMC) Conference*, 2020, pp. 292–299.

- [G] S. Willemsen, S. Bilbao, M. Ducceschi, and S. Serafin, “Dynamic grids for finite-difference schemes in musical instrument simulations,” in *Proceedings of the 23rd International Conference on Digital Audio Effects (DAFx2020in21)*, 2021.
- [H] —, “A physical model of the trombone using dynamic grids for finite-difference schemes,” in *Proceedings of the 23rd International Conference on Digital Audio Effects (DAFx2020in21)*, 2021.

Publications with a Supervisory Role

- [S1] R. S. Alecu, S. Serafin, S. Willemsen, E. Parravicini, and S. Lucato, “Embouchure interaction model for brass instruments,” in *Proceedings of the 17th Sound and Music Computing (SMC) Conference*, 2020, pp. 153–160.
- [S2] T. Lasickas, S. Willemsen, and S. Serafin, “Real-time implementation of the shamisen using finite difference schemes,” in *Proceedings of the 18th Sound and Music Computing (SMC) Conference*, 2021.
- [S3] M. G. Onofrei, S. Willemsen, and S. Serafin, “Implementing complex physical models in real-time using partitioned convolution: An adjustable spring reverb,” in *Proceedings of the 18th Sound and Music Computing (SMC) Conference*, 2021.
- [S4] —, “Real-time implementation of an elasto-plastic friction drum using finite difference schemes,” in *Proceedings of the 23rd International Conference on Digital Audio Effects (DAFx2020in21)*, 2021.

Miscellaneous Publications

- [M1] J. M. Hjerrild, S. Willemsen, and M. G. Christensen, “Physical models for fast estimation of guitar string, fret and plucking position,” *IEEE Workshop on Applications of Signal Processing to Audio and Acoustics (WASPAA)*, pp. 155–159, 2019.
- [M2] K. Prawda, S. Willemsen, S. Serafin, and V. Välimäki, “Flexible real-time reverberation synthesis with accurate parameter control,” in *Proceedings of the 23rd International Conference on Digital Audio Effects (DAFx-20)*, 2020.
- [M3] M. Ducceschi, S. Bilbao, S. Willemsen, and S. Serafin, “Linearly-implicit schemes for collisions in musical acoustics based on energy quadratisation,” *Journal of the Acoustical Society of America (JASA)*, 2021.

Preface

Starting this Ph.D. project, I did not have a background in mathematics, physics or computer science, which were three equally crucial components in creating the result of this project. After the initial steep learning curve of notation and terminology, I was surprised to find that the methods used for physical modelling are actually quite straightforward!

Of course it should take a bit of time to learn these things, but

Many concepts that seemed impossible at the beginning

I feel that the literature lacks a lot of the intuition needed for readers without a background in any of these topics. Rather, much of the literature I came across assumes that the reader has a degree in at least one of the aforementioned topics. This is why I decided to write this work a bit more pedagogical than what could be expected.

I believe that anyone with some basic skills in mathematics and programming is able to create a simulation based on physics within a short amount of time, given the right tools, which I hope that this dissertation could be.

The knowledge dissemination of this dissertation is thus not only limited to the research done and publications made over the course of the project, but also its pedagogical nature hopefully allowing future (or past) students to benefit from.

As with a musical instrument itself, a low entry level, a gentle learning curve along with a high virtuosity level is desired. Take a piano, for instance. Most will be able to learn a simple melody — such as “Frère Jacques” — in minutes, but to become virtuous requires years of practice.

This is the way I wanted to write this dissertation: easy to understand the basic concepts, but many different aspects touched upon to allow for virtuosity. Hopefully by the end, the reader will at least grasp some highly complex concepts in the fields of mathematics, physics and computer science (which will hopefully take less time than it takes to become virtuous at playing the piano).

Some basic calculus knowledge is assumed.

I wanted to show my learning process and (hopefully) explain topics such as *Energy Analysis*, *Stability Analysis*, etc. in a way that others lacking the same

Preface

knowledge will be able to understand.

Make physical modelling more accessible to the non-physicist.

Interested in physically impossible manipulations of now-virtual instruments.

Silvin Willemsen

Part I

Introduction

Chapter 1

Physical Modelling of Musical Instruments

The history of physical modelling of musical instruments

Exciter-resonator approach.

The time-evolution of dynamic systems can be conveniently described by differential equations. Examples of a dynamic systems are a guitar string, a drum-membrane, or a concert hall; three very different concepts, but all based on the same types of equations of motion.

Though these equations are very powerful, only few have a closed-form solution. What this means is that in order for them to be implemented, they need to be approximated. There exist different approximation techniques to do this

1.1 Physical Modelling Techniques

- Modal Synthesis
- Finite-difference Time-domain methods
- Finite Element Methods
- Digital waveguides
- Mass-spring systems
- Functional transformation method
- State-space
- Wave-domain

- Energy-based

Advantages of finite-difference methods

Using FDTD methods can be quite computationally heavy. Moore's law [13]

1.2 Real-Time Implementation

Although many techniques to digitally simulate musical instruments exist proving that we have only recently reached the computing power in personal computers to make real-time playability of these models an option. The biggest challenge in real-time audio applications as opposed to those only involving graphics, is that the sample rate is extremely high. As Nyquist's sampling theory tells us, a sampling rate of at least 40 kHz is necessary to produce frequencies up to the human hearing limit of 20 kHz [Nyquist]. Visuals

Real-time: no noticeable latency

1.3 Why?

1.3.1 Audio plugins

Samples, or recordings, of real instruments are static and unable to adapt to changes in performance. Moreover, capturing the entire interaction space of an instrument is nearly impossible. Imagine recording a violin with every single combination of bowing force, velocity, position, duration and other aspects such as vibrato, pizzicato. Even if a complete sample library could be created, this would contain an immense amount of data.

Samples vs. Physical Modelling:

Trade off between storage and speed

Using musical instrument simulations, on the other hand, allows the sound to be generated on the spot based on physical parameters that the user can interact with.

1.3.2 Resurrect old or rare instruments

Even popular instruments require maintenance and might need to be replaced after years of usage.

1.3.3 Go beyond what is physically possible

exactly as in
[3]

1.4 Thesis Objectives and Main Contributions

Over the past few decades, much work has been done on the accurate modelling of physical phenomena. In the field of sound and musical instruments..

From [7] to [5]

The main objective of this thesis is to implement existing physical models in real time using FDTD methods. Many of the physical models and methods presented in this thesis are taken from the literature and are thus not novel.

Secondly, to combine the existing physical models to get complete instruments and be able to control them in real time.

As FDTD methods are quite rigid, changing parameters on the fly, i.e., while the instrument simulation is running, is a challenge. Other techniques, such as modal synthesis, are much more suitable for this, but come with the drawbacks mentioned in Section 1.1. Therefore, a novel method was devised to smoothly change parameters over time, introducing this to FDTD methods.

Put this work into perspective of the literature (higher level)

1.5 Thesis Outline

Introduction to finite-difference methods and analysis techniques

Models used over the course of the project divided into resonators in part II, exciters in part III and the interactions between them in IV.

Focus on real-time implementation and control of the models in part VI

- Physical models
 - Resonators
 - Exciters
 - Interactions
- Dynamic Grids
- Real-Time Implementation and Control
- Complete instruments
 - Large-scale physical models
 - Tromba Marina
 - Trombone

Notes

- Think about how to define real-time.
- Create an intuition for different parts of the equation
- Talk about input and output locations and how that affects frequency content (modes).

One over number \rightarrow reciprocal of number

Example: When the waveform consists entirely of harmonically related frequencies, it will be periodic, with a period equal to the reciprocal of the fundamental frequency (from An Introduction to the Mathematics of Digital Signal Processing Pt 2 by F. R. Moore)

Chapter 2

FDTD Methods and Analysis Techniques

“Since Newton, mankind has come to realize that the laws of physics are always expressed in the language of differential equations.”
- Steven Strogatz

This chapter introduces some important concepts needed to understand the physical models presented later on in this document. By means of a simple mass-spring system and the 1D wave equation, the notation and terminology used throughout this document will be explained, together with some important analysis techniques. Before diving into the mathematics, let us go over some useful terminology.

2.1 Differential Equations

Differential equations are used to describe the motion of dynamic systems including vibrations in musical instruments. In this work, these equations are used, among others, to describe the movement of a string, an instrument body and the air pressure in an acoustic tube.

A characteristic feature of these equations is that, rather than an absolute value or *state* of a system, the time derivative of its state – its velocity – or the second time derivative – its acceleration – is described. From this, the absolute state of the system can then be computed. This state is usually described by the variable u which is (nearly) always a function of time, i.e., $u = u(t)$. If the system is distributed in space, u also becomes a function of space, i.e., $u = u(x, t)$, or with two spatial dimensions, $u = u(x, y, t)$, etc. Though this

work only describes systems of up to two spatial dimensions, one can easily extend to three dimensions [10] and potentially higher-dimensional systems [14]!

If u is univariate, and only a function of time, the differential equation that describes the motion of this system is called an *ordinary differential equation* (ODE). Various ways to describe the second derivative in time of u , or the acceleration of u are

$$\frac{d^2 u}{dt^2} \quad (\text{Leibniz's notation}),$$

$$\ddot{u} \quad (\text{Newton's notation}),$$

$$D_t^2 u \quad (\text{Euler's notation}).$$

Leibniz' notation could be considered the most standard notation but is not necessarily compact. Newton's notation on the other hand allows for an ultra compact notation using a dot above the function to denote a derivative. However, this notation can only be used for univariate functions which it will be used for in this document. Finally, Euler's notation uses an operator which can be applied to a function and indicates a derivative.

If u is also a function of at least one spatial dimension, the equation of motion is called a *partial differential equation* (PDE). The literature uses different types of notation for taking (continuous-time) partial derivatives. Applied to a state variable u these can look like

$$\frac{\partial^2 u}{\partial t^2} \quad (\text{Leibniz's notation})$$

$$u_{tt} \quad (\text{subscript notation})$$

$$\partial_t^2 u \quad (\text{Euler's notation})$$

where the subscript notation could be seen as the partial derivative counterpart to Newton's notation due to its compactness. In the remainder of this document, the operator notation will be used, due to their similarity to the discrete operators (introduced shortly) and as it allows for creation of bigger operators for more compactness when working with multiple (connected) systems (see e.g. Chapter 14). Often-used partial derivatives and their meanings are shown below

$$\partial_t^2 u \quad (\text{acceleration})$$

$$\partial_t u \quad (\text{velocity})$$

$$\partial_x^2 u \quad (\text{curvature})$$

$$\partial_x u \quad (\text{slope})$$

Note on dimensions

It is important to notice that there is a difference between a system described over multiple spatial dimensions, such as a membrane, or a plate, and a system state having multiple coordinates. In much of the literature on FDTD methods

in the field of musical acoustics, the state variable only describes one coordinate. In most string models, for example, only the transverse displacement is considered (see Chapter 3) and the longitudinal motion of the string is ignored. In other words, every point along the string can only move up and down, not side-to-side. Although this greatly simplifies the system at hand, this is not what happens in reality, and effects such as phantom partials and pitch glides due to tension modulation are not present in the simplified model.

Models exist that take longitudinal vibration into account... SOTA

Luckily, these single-polarisation models (under low amplitudes) already give

though work has been done on strings with dual polarisation [6] In this work, *Note: difference between 1D, 2D spatial, and 1D, 2D displacement (polarisation). Transverse displacement of 1D wave here*

2.2 Discretisation using FDTD methods

Differential equations are powerful tools that describe the motion of physical systems. Despite this, only few of these have a closed-form or analytical solution (such as the simpler ones that will be presented in this chapter). More complex systems require methods that do not perfectly solve, but rather approximate the solutions to these equations. Finite-difference time-domain (FDTD) are considered one of the in terms of generality and flexibility...

It is important to note that a discrete FD scheme is an approximation to a continuous PDE, not a sampled version of it. This means that the resulting schemes are rarely an exact solution to the original continuous equation.

These methods essentially subdivide a continuous differential equation into discrete points in time and space, a process called *discretisation*. Once an ODE or PDE is discretised using these methods it is now called a *finite-difference (FD) scheme* which approximates the original differential equation.

Fig. 2.1: A continuous PDE is discretised

different word-
ing in caption

2.2.1 Grid Functions

We start by defining a discrete *grid* over time and space which we will use to approximate our continuous equations. A system $u = u(x, t)$ defined over time t and one spatial dimension x , can be approximated using a *grid function* u_l^n . Here, subscript l and superscript n describe the spatial and temporal indices respectively and arise from the discretisation of the continuous variables x and t according to $x = lh$ and $t = nk$. The spatial step h , also called the *grid spacing* describes the distance (in m) between two neighbouring grid points and the temporal step k , or *time step* is the time (in s) between two consecutive temporal indices. The latter can be calculated $k = 1/f_s$ for a sample rate f_s (in Hz). In many audio applications $f_s = 44100$ Hz which will be used in this work (unless denoted otherwise).

To summarise

$$u(x, t) \approx u_l^n \quad \text{with} \quad x = lh \quad \text{and} \quad t = nk \quad (2.1)$$

2.2.2 Finite-Difference Operators

Now that the state variable has a discrete counterpart, this leaves the derivatives to be discretised, or approximated. We start by introducing shift operators that can be applied to a grid function and ‘shifts’ its indexing, either spatial or temporal. Forward and backward shifts in time, together with the identity operation are

$$e_{t+} u_l^n = u_l^{n+1}, \quad e_{t-} u_l^n = u_l^{n-1}, \quad \text{and} \quad 1 u_l^n = u_l^n. \quad (2.2)$$

Similarly, forward and backward shifts in space are

$$e_{x+} u_l^n = u_{l+1}^n, \quad \text{and} \quad e_{x-} u_l^n = u_{l-1}^n. \quad (2.3)$$

These shift operators are rarely used in isolation, though they do appear in energy analysis techniques detailed in Section 2.5. The operators do, however, form the basis of commonly used *finite-difference (FD) operators*. The first-order derivative in time can be discretised three different ways. The forward, backward and centred difference operators are

$$\partial_t \approx \begin{cases} \delta_{t+} \triangleq \frac{1}{k} (e_{t+} - 1), & (2.4a) \\ \delta_{t-} \triangleq \frac{1}{k} (1 - e_{t-}), & (2.4b) \\ \delta_{t\cdot} \triangleq \frac{1}{2k} (e_{t+} - e_{t-}), & (2.4c) \end{cases}$$

where “ \triangleq ” means “equal to by definition”. These operators can then be applied to grid function u_l^n to get

$$\partial_t u \approx \begin{cases} \delta_{t+} u_l^n = \frac{1}{k} (u_l^{n+1} - u_l^n), & (2.5a) \\ \delta_{t-} u_l^n = \frac{1}{k} (u_l^n - u_l^{n-1}), & (2.5b) \\ \delta_{t\cdot} u_l^n = \frac{1}{2k} (u_l^{n+1} - u_l^{n-1}), & (2.5c) \end{cases}$$

2.2. Discretisation using FDTD methods

and all approximate the first-order time derivative of u . Note that the centred difference has a division by $2k$ as the time difference between $n + 1$ and $n - 1$ is, indeed, twice the time step.

Similar operators exist for a first-order derivative in space, where the forward, backward and centred difference are

figure here visualising operators (with reference to grid figure)

$$\partial_x \approx \begin{cases} \delta_{x+} \triangleq \frac{1}{h} (e_{x+} - 1), & (2.6a) \\ \delta_{x-} \triangleq \frac{1}{h} (1 - e_{x-}), & (2.6b) \\ \delta_{x\cdot} \triangleq \frac{1}{2h} (e_{x+} - e_{x-}), & (2.6c) \end{cases}$$

and when applied to u_l^n are

$$\partial_x u \approx \begin{cases} \delta_{x+} u_l^n = \frac{1}{h} (u_{l+1}^n - u_l^n), & (2.7a) \\ \delta_{x-} u_l^n = \frac{1}{h} (u_l^n - u_{l-1}^n), & (2.7b) \\ \delta_{x\cdot} u_l^n = \frac{1}{2h} (u_{l+1}^n - u_{l-1}^n). & (2.7c) \end{cases}$$

Higher order differences can be approximated through a composition of first-order difference operators. The second-order difference in time may be approximated using

$$\partial_t^2 \approx \delta_{t+} \delta_{t-} = \delta_{tt} \triangleq \frac{1}{k^2} (e_{t+} - 2 + e_{t-}), \quad (2.8)$$

where “2” is the identity operator applied twice. and similarly for the second-order difference in space

$$\partial_x^2 \approx \delta_{x+} \delta_{x-} = \delta_{xx} \triangleq \frac{1}{h^2} (e_{x+} - 2 + e_{x-}). \quad (2.9)$$

Further information on combining operators can be found in Section 3.2.1.

Also useful are averaging operators, all of which approximate the identity operator. The temporal forward, backward and centred averaging operators are

in energy analysis, interleaved grids, etc.

$$1 \approx \begin{cases} \mu_{t+} \triangleq \frac{1}{2} (e_{t+} + 1), & (2.10a) \\ \mu_{t-} \triangleq \frac{1}{2} (1 + e_{t-}), & (2.10b) \\ \mu_{t\cdot} \triangleq \frac{1}{2} (e_{t+} + e_{t-}). & (2.10c) \end{cases}$$

Notice how these definitions are different than the difference operators in (2.4): the terms in the parentheses are added rather than subtracted, and rather than a division by the time step k there is a division by 2. Finally, the centred averaging operator does not have an extra division by 2 as in (2.4c). Applied to u_l^n , Eqs. (2.10) become

$$u_l^n \approx \begin{cases} \mu_{t+} u_l^n = \frac{1}{2} (u_l^{n+1} + u_l^n), & (2.11a) \\ \mu_{t-} u_l^n = \frac{1}{2} (u_l^n + u_l^{n-1}), & (2.11b) \\ \mu_{t\cdot} u_l^n = \frac{1}{2} (u_l^{n+1} + u_l^{n-1}). & (2.11c) \end{cases}$$

Similarly, spatial averaging operators are

$$1 \approx \begin{cases} \mu_{x+} \triangleq \frac{1}{2} (e_{x+} + 1), & (2.12a) \\ \mu_{x-} \triangleq \frac{1}{2} (1 + e_{x-}), & (2.12b) \\ \mu_{x\cdot} \triangleq \frac{1}{2} (e_{x+} + e_{x-}), & (2.12c) \end{cases}$$

and when applied to u_l^n

$$u_l^n \approx \begin{cases} \mu_{x+} u_l^n = \frac{1}{2} (u_{l+1}^n + u_l^n), & (2.13a) \\ \mu_{x-} u_l^n = \frac{1}{2} (u_l^n + u_{l-1}^n), & (2.13b) \\ \mu_{x\cdot} u_l^n = \frac{1}{2} (u_{l+1}^n + u_{l-1}^n). & (2.13c) \end{cases}$$

Operators and derivatives in 2D will be discussed in Chapter 5.

Accuracy

As FDTD methods approximate continuous systems, the resulting solution is rarely 100% accurate. To determine the accuracy of the FD operators above, one can perform a Taylor series analysis. The Taylor series is an infinite sum and its expansion of a function f about a point a is defined as

$$f(x) = \sum_{n=0}^{\infty} \frac{(x-a)^n}{n!} f^{(n)}(a) \quad (2.14)$$

where superscript (n) denotes the n^{th} derivative of f with respect to x . The analysis will be performed on the temporal operators in Eqs. (2.4) and (2.8), but also apply to the spatial operators in Eqs. (2.7) and (2.9).

Using continuous function $u = u(t)$ and following Bilbao's "slight abuse of notation" in [3], one may apply FD operators to continuous functions according to

$$\delta_{t+} u(t) = \frac{u(t+k) - u(t)}{k}. \quad (2.15)$$

Assuming that u is infinitely differentiable, $u(t+k)$, i.e., u at the next time step (but in continuous time), can be approximated using a Taylor series expansion of u about t according to

$$u(t+k) = u(t) + k\dot{u} + \frac{k^2}{2}\ddot{u} + \frac{k^3}{6}\ddot{\dot{u}} + \mathcal{O}(k^4). \quad (2.16)$$

Here, (following Newton's notation) the dot describes a single temporal derivative and \mathcal{O} includes additional terms in the expansion. The power of k in the argument of \mathcal{O} describes the order of the error, which is lowest power of k (as $k < 1$). Equation (2.16) can be rewritten to

$$\begin{aligned} \frac{u(t+k) - u(t)}{k} &= \dot{u} + \frac{k}{2}\ddot{u} + \frac{k^2}{6}\ddot{\dot{u}} + \mathcal{O}(k^3), \\ \dot{u} &= \frac{u(t+k) - u(t)}{k} + \mathcal{O}(k), \end{aligned} \quad (2.17)$$

2.2. Discretisation using FDTD methods

is the definition of the forward operator in time in Eq. (2.15) but with an additional error term. Notice that the sign of \mathcal{O} does not matter. As the power of k in \mathcal{O} 's argument determines the order of the error of the approximation, we can conclude that the forward operator is first-order accurate. One can also observe that, as expected, the error gets smaller as the time step k gets smaller and indicates that higher sample rates result in more accurate simulations (through $k = 1/f_s$).

We can arrive at a similar result for the backward operator. Applying Eq. (2.4b) to u yields

$$\delta_{t-}u(t) = \frac{u(t) - u(t-k)}{k} \quad (2.18)$$

and performing a Taylor series expansion of u about t yields

$$u(t-k) = u(t) + (-k)\dot{u} + \frac{(-k)^2}{2}\ddot{u} + \frac{(-k)^3}{6}\ddot{\dot{u}} + \mathcal{O}(k^4), \quad (2.19)$$

$$\begin{aligned} \frac{u(t-k) - u(t)}{k} &= -\dot{u} + \frac{k}{2}\ddot{u} - \frac{k^2}{6}\ddot{\dot{u}} + \mathcal{O}(k^3), \\ \dot{u} &= \frac{u(t) - u(t-k)}{k} + \mathcal{O}(k). \end{aligned} \quad (2.20)$$

Applying the centred operator in Eq. (2.4c) to u yields

$$\delta_t.u(t) = \frac{u(t+k) - u(t-k)}{2k}, \quad (2.21)$$

indicating that to find the order of accuracy for this operator, both Eqs. (2.16) and (2.19) are needed. Subtracting these and filling in their definitions yields

$$u(t+k) - u(t-k) = 2k\dot{u} - \frac{2k^3}{6}\ddot{\dot{u}} + 2\mathcal{O}(k^5), \quad (2.22)$$

$$\frac{u(t+k) - u(t-k)}{2k} = \dot{u} - \frac{k^2}{6}\ddot{\dot{u}} + \mathcal{O}(k^4), \quad (2.23)$$

$$\dot{u} = \frac{u(t+k) - u(t-k)}{2k} + \mathcal{O}(k^2). \quad (2.24)$$

Notice that due to several terms cancelling out, the centred difference operator is second-order accurate.

As a first-order derivative indicates the *slope* of a function, the differences in accuracy between the above operators can be visualised as such (see Figure 2.2). It can be observed that the derivative approximation of the centred operator much more closely matches the the true derivative of u at t .

Finally, the second-order difference in time operator in Eq. (2.8) can be

Fig. 2.2: The accuracy of the forward, backward and centred difference operators in (2.4) visualised. One can observe that the centred difference operator much more closely approximates the derivative, or the slope, of u at t than the forward and backward difference operators.

proven to be second-order accurate as well by adding Eqs. (2.16) and (2.19):

$$\begin{aligned}
 u(t+k) + u(t-k) &= 2u(t) + k^2 \ddot{u} + \mathcal{O}(k^4), \\
 \frac{u(t+k) - 2u(t) + u(t-k)}{k^2} &= \ddot{u} + \mathcal{O}(k^2), \\
 \ddot{u} &= \frac{u(t+k) - 2u(t) + u(t-k)}{k^2} + \mathcal{O}(k^2). \quad (2.25)
 \end{aligned}$$

2.2.3 Identities

For working with FD schemes, either for implementation or analysis, it can be extremely useful to rewrite the operators presented above to equivalent versions of themselves. These are called identities and for future reference, some useful ones are listed below

$$\delta_{tt} = \frac{2}{k} (\delta_{t-} - \delta_{t+}) \quad (2.26a)$$

$$\delta_{t-} = \delta_{t+} \mu_{t-} = \delta_{t-} \mu_{t+} \quad (2.26b)$$

$$\mu_{t+} = \frac{k}{2} \delta_{t+} + 1 \quad (2.26c)$$

That these equalities hold can easily be proven by expanding the operators defined in Section 2.2.2. Naturally, these identities also hold for spatial operators by simply substituting the ‘ t ’ subscripts for ‘ x ’.

2.3 The Mass-Spring System

Though a complete physical modelling field on its own (see Chapter 1), mass-spring systems are also sound-generating systems themselves and lend themselves well to illustrating and explaining FDTD methods in practice. Starting

see whether the negative version of identity (2.26c) is also used later on

2.3. The Mass-Spring System

with the continuous-time ODE, this section continues to discretise it to an FD scheme using the operators described in Section 2.2.2. Finally, the scheme is rewritten to an update equation that can be implemented and the output of the system is shown.

2.3.1 Continuous-time

Using dots to indicate a temporal derivative, the ODE of a simple mass-spring system is defined as

$$M\ddot{u} = -Ku, \quad (2.27)$$

where $u = u(t)$ is the distance from the equilibrium position (in m), $M > 0$ is the mass of the mass (in kg) and $K \geq 0$ is the spring constant (in N/m). In the literature [3, ?], Eq. (2.27) is often written as

$$\ddot{u} = -\omega_0^2 u \quad (2.28)$$

with

$$\omega_0 = \sqrt{K/M}. \quad (2.29)$$

This way of writing the mass-spring ODE is more compact and more straightforward to relate to a fundamental frequency $f_0 = \omega_0/2\pi$ (in Hz).

Apart from the choices of K and M , the behaviour of the mass-spring system is determined by its *initial conditions*, being $u(0)$ and $\partial_t u(0)$, i.e., the displacement and velocity of the mass at $t = 0$. If the initial conditions are non-zero, the path that the mass follows over time is sinusoidal (see Figure 2.3), which is also why the mass-spring system is often referred to as the *simple harmonic oscillator*. The amplitude of the sinusoid is determined by the initial conditions, whereas the frequency is determined by M and K .

Intuition

The behaviour of the mass-spring system in Eq. (2.27) arises from two basic laws of physics: *Newton's second law* and *Hooke's law*.

Fig. 2.3: Mass spring system over time. The system follows a harmonic (sinusoidal) motion.

Starting with Newton's second law *force equals mass times acceleration*, and relating this to the variables used in Eq. (2.27) yields an expression for force

$$F = M\ddot{u}. \quad (2.30)$$

This equation in isolation can be used to, fx., calculate the force necessary to accelerate a mass of M kg to \ddot{u} m/s². Next, the force generated by the spring follows Hooke's law:

$$F = -Ku, \quad (2.31)$$

which simply states that the force generated by a spring with stiffness K is negatively proportional to the value of u . In other words, the further the spring is extended (from the equilibrium $u = 0$), the more force will be generated in the opposite direction. Finally, as the sole force acting on the mass is the one generated by the spring, the two expressions for the force F can be set equal to each other and yields the equation for the mass-spring system in (2.27).

The sinusoidal behaviour of the mass-spring system, or a least the fact that the mass "gets pulled back" to the equilibrium, is apparent from the minus-sign in Eq. (2.31). The frequency of the sinusoid, depends on the value of K as the "pull" happens to a higher degree for a higher spring stiffness. That the frequency of the system is also dependent on the mass M can be explained by the fact that a lighter object is more easily moved and vice versa, which is apparent from Eq. (2.30). In other words, the pull of the spring has a greater effect on the acceleration of a lighter object than a heavier one.

Finally, if $u = 0$ there is no spring force present and the acceleration remains unchanged. If the mass is not in motion, this means that it remains stationary, but if it is, the velocity is unchanged and it will continue moving with the same speed.

2.3.2 Discrete-time

The displacement of the mass is approximated using

$$u(t) \approx u^n, \quad (2.32)$$

with time $t = nk$, time step $k = 1/f_s$, sample rate f_s and temporal index and $n \in \mathbb{N}^0$.¹ Note that the "grid function" does not have a subscript l as u is not distributed in space and is now simply called a *time series*.

Using the operators found in Section 2.2.2, Eq. (2.27) can be discretised as follows:

$$M\delta_{tt}u^n = -Ku^n, \quad (2.33)$$

which is the first appearance of a FD scheme in this work. Expanding the δ_{tt} operator yields

$$\frac{M}{k^2} (u^{n+1} - 2u^n + u^{n-1}) = -Ku^n,$$

¹In this work, \mathbb{N}^0 is used to denote the set of non-negative integers ($\mathbb{N}^0 = 0, 1, 2, \dots$).

2.3. The Mass-Spring System

and solving for u^{n+1} results in the following recursion or *update equation*:

$$u^{n+1} = 2u^n - u^{n-1} - \frac{Kk^2}{M}u^n, \quad (2.34)$$

which can be implemented in a programming language such as MATLAB or C++.

To be able to calculate the scheme at $n = 0$ (the first time index of the simulation), values must be provided for u^0 and u^{n-1} . These are determined by the initial conditions. A simple way to obtain a sinusoidal motion with an amplitude of 1, is to set the initial conditions as follows (using the backwards time difference operator for discretising the first-order time derivative):

$$u^0 = 1 \quad \text{and} \quad \delta_{t-}u^n = 0. \quad (2.35)$$

The latter equality can be solved for u^{-1} to obtain its definition:

$$\begin{aligned} \frac{1}{k} (u^0 - u^{-1}) &= 0, \\ \xLeftrightarrow{u^0=1} 1 - u^{-1} &= 0, \\ u^{-1} &= 1. \end{aligned}$$

Simply setting $u^0 = u^{-1} \neq 0$ yields an oscillatory behaviour.

maybe a bit short...

2.3.3 Implementation and Output

A simple MATLAB script implementing the mass-spring system described in this section is shown in Appendix C.1. The output of the system can be obtained by listening to the displacement of the mass at the given sample rate f_s . An example of this can be found in Figure 2.4 where the frequency of oscillation $f_0 = 440$ Hz.

Fig. 2.4: The time-domain and frequency-domain output of a mass-spring system with $f_0 = 440$ Hz.

Time-domain and FFT figs

add damping?

2.4 The 1D Wave Equation

Arguably the most important PDE in the field of physical modelling for sound synthesis is the 1D wave equation.

2.4.1 Continuous-time

The state of the system $u = u(x, t)$ meaning that is on top of being defined in time t it is distributed over space x . The 1D wave equation is defined as follows

$$\partial_t^2 u = c^2 \partial_x^2 u, \quad (2.36)$$

where c is the wave speed (in m/s). The state variable u can be used to describe transverse vibration in an ideal string, longitudinal vibration in an ideal bar and pressure in an acoustic tube. Although the behaviour of this equation alone does not appear in the real world, as no physical system is ideal, it is extremely useful as a test case and a basis for more complicated models. Here, it will be used to introduce various concepts and analysis techniques in the field of FDTD methods.

Intuition

Although the 1D wave equation often appears in the literature, an intuition or interpretation of why it works the way it does is hard to find. In the following, u describes the transverse displacement of an ideal string.

OR

I would like to use this opportunity to provide some extra explanation as to how and why the 1D wave equation in (2.36) works the way it does. This will hopefully provide some basic intuition into the workings of PDEs that will make it easier to work with later on. [something something](#)

Going back to Newton's second law

The acceleration of $u = u(x, t)$ at location x is determined by the second-order spatial derivative of u at that same location (scaled by a constant c^2). In the case that u describes the transverse displacement of an ideal string, this second-order derivative denotes the *curvature* of this string. As c^2 is always positive, the sign (or direction) of the acceleration is fully determined by the sign of the curvature. In other words, a 'positive' curvature at location x along the ideal string yields a 'positive' or upwards acceleration at that same location.

What a 'positive' or 'negative' curvature implies is more easily seen when we take a simple function describing a parabola, $y(x) = x^2$, and take its second derivative to get $y''(x) = 2$. The answer is a positive number which means that y has a positive curvature.

So, what does this mean for the 1D wave equation? As a positive curvature implies a positive or upwards acceleration as per Eq. (2.36), u with a positive

2.4. The 1D Wave Equation

curvature at a location x will start to move upwards and vice versa. Of course, the state of a physical system such as u will rarely have a perfect parabolic shape, but the argument still applies.

Fig. 2.5: The forces acting on the 1D wave equation due to curvature. The arrows indicate the direction and magnitude of the force, and simultaneously the acceleration as these are connected through Eq. (2.36).

different wording in caption

Boundary Conditions

When a system is distributed in space,

For analysis purposes, an infinite domain may be adopted, but for implementation, a finite domain needs to be established.

Consider a system of length L (in m) $x \in \mathcal{D}$ (x is an element in \mathcal{D}) where domain $\mathcal{D} = [0, L]$ Two alternatives are

$$u(0, t) = u(L, t) = 0 \quad (\text{Dirichlet, fixed}), \quad (2.37a)$$

$$\partial_x u(0, t) = \partial_x u(L, t) = 0 \quad (\text{Neumann, free}), \quad (2.37b)$$

2.4.2 Discrete-time

The most straightforward discretisation of Eq. (2.36) is the following FD scheme

$$\delta_{tt} u_l^n = c^2 \delta_{xx} u_l^n. \quad (2.38)$$

Other schemes exist (such as implicit)

Stability

The parameters that define (2.38) are linked through a stability condition. The famous Courant-Friedrichs-Lewy or *CFL condition* is defined as [?]

$$\lambda \leq 1 \quad \text{where} \quad \lambda = \frac{ck}{h} \quad (2.39)$$

where

$$\lambda = \frac{ck}{h} \quad (2.40)$$

is referred to as the *Courant number*.

Regarding implementation, as the time step k is based on the sample rate and thus usually fixed and c is a user-defined wavespeed, it is useful to rewrite Eq. (2.39) to be in terms of the grid spacing h :

$$h \geq ck. \quad (2.41)$$

The number of grid points can then be calculated using

$$h := ck, \quad N = \left\lfloor \frac{L}{h} \right\rfloor, \quad h := \frac{L}{N} \quad \lambda = \frac{ck}{h}. \quad (2.42)$$

where $\lfloor \cdot \rfloor$ denotes the flooring operation.

Implementation

$$u_l^{n+1} = 2u_l^n - u_l^{n-1} + \lambda^2 (u_{l+1}^n - 2u_l^n + u_{l-1}^n) \quad (2.43)$$

If $\lambda = 1$, (2.38) is an exact solution to Eq. (2.36). This is no

Numerical Dispersion

2.4.3 Output

After the system is excited (see III), one can listen to the output

The location, or frequency of the harmonic partials can also be analytically / numerically derived using modal analysis as will be explained in 2.7.

The amplitude of the different modes, on the other hand, depends on the location of excitation and output.

2.4.4 Matrix Form

For several purposes, such as implementation in MATLAB and several analysis techniques described shortly, is useful to write an FD scheme in *matrix form*.

In this document, matrices and vectors are written using bold symbols. Many notations exist, blabla \bar{a} A matrix uses a capital letter whereas vectors are decapitalised. The dimensions of a matrix are denoted using “*row* \times *column*”. A 6×14 matrix, for example, thus has 6 rows and 14 columns. Along those lines, a *row vector* is a matrix with 1 row and more than 1 column and a *column vector* is a matrix with 1 column and more than 1 row. If a matrix has only 1 row and 1 column, it can be used as a *scalar*.

Matrix Multiplication

In order for matrix multiplication (including matrix-vector multiplication) to be valid, the number of columns of the first matrix needs to be equal to the number of rows in the second matrix. The result will then be a matrix with a number of rows equal to that of the first matrix and a number of columns equal to that of the second matrix. See Figure ?? for reference.

As an example, consider the $L \times M$ matrix **A** and a $M \times N$ matrix **B**. The multiplication **AB** is defined as the number of columns of matrix **A** (M) is equal to the number of rows of matrix **B** (also M). The result, **C**, is a $L \times N$ matrix. The multiplication **BA** is undefined as the number of columns of the first matrix does not match the number of rows in the second matrix.

Multiplying two matrices written in their dimensions as

$$\overbrace{(L \times M)}^{\mathbf{A}} \cdot \overbrace{(M \times N)}^{\mathbf{B}} = \overbrace{(L \times N)}^{\mathbf{C}} \quad (2.44)$$

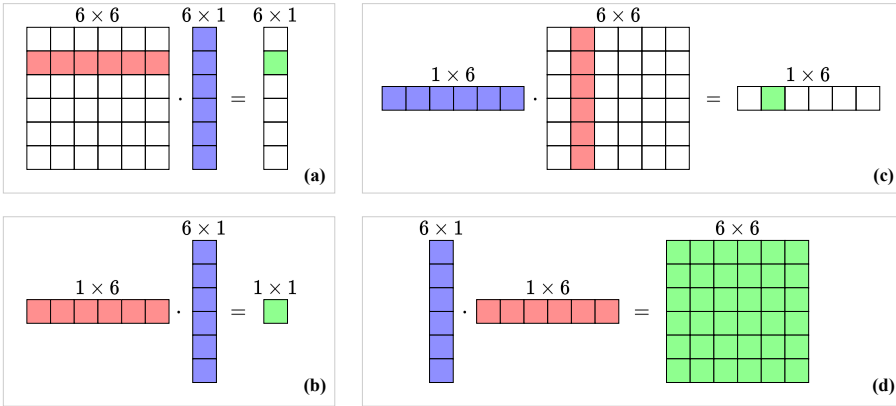

Fig. 2.6: Visualisation of valid matrix(-vector) multiplications.

In a FDTD context

Matrix multiplication when working with FDTD methods usually involves multiplying a square matrix (with equal rows and columns) onto a column vector (see Figure 2.6a). Consider a square matrix with $(N + 1) \times (N + 1)$ elements **A** and a $(N + 1) \times 1$ column vector **u**. Multiplying these results in a $(N + 1) \times 1$ column vector **w**:

$$\mathbf{A}\mathbf{u} = \mathbf{w}. \quad (2.45)$$

Expanding this operation results in

$$\underbrace{\begin{bmatrix} a_{00} & a_{01} & \dots & a_{0N} \\ a_{10} & a_{11} & \dots & a_{2N} \\ \vdots & \vdots & & \vdots \\ a_{N0} & a_{N1} & \dots & a_{NN} \end{bmatrix}}_{\mathbf{A}} \underbrace{\begin{bmatrix} u_0 \\ u_1 \\ \vdots \\ u_N \end{bmatrix}}_{\mathbf{u}} = \underbrace{\begin{bmatrix} a_{00}u_0 + a_{01}u_1 + \dots + a_{0N}u_N \\ a_{10}u_0 + a_{11}u_1 + \dots + a_{1N}u_N \\ \vdots \\ a_{N0}u_0 + a_{N1}u_1 + \dots + a_{NN}u_N \end{bmatrix}}_{\mathbf{w}} \quad (2.46)$$

Operators in Matrix Form

The FD operators approximating first-order spatial derivatives in (2.7) can be written in matrix form according to

$$\mathbf{D}_{x+} = \frac{1}{h} \begin{bmatrix} \ddots & \ddots & & & \mathbf{0} \\ & -1 & 1 & & \\ & & -1 & 1 & \\ & & & -1 & 1 \\ & & & & -1 & \ddots \\ \mathbf{0} & & & & & \ddots \end{bmatrix} \quad \mathbf{D}_{x-} = \frac{1}{h} \begin{bmatrix} \ddots & & & & \mathbf{0} \\ \ddots & 1 & & & \\ & -1 & 1 & & \\ & & -1 & 1 & \\ & & & -1 & 1 \\ \mathbf{0} & & & & \ddots & \ddots \end{bmatrix}$$

$$\mathbf{D}_{x\cdot} = \frac{1}{2h} \begin{bmatrix} \ddots & \ddots & & & \mathbf{0} \\ \ddots & 0 & 1 & & \\ & -1 & 0 & 1 & \\ & & -1 & 0 & 1 \\ & & & -1 & 0 & \ddots \\ \mathbf{0} & & & & \ddots & \ddots \end{bmatrix}$$

The matrices \mathbf{D}_{x+} and \mathbf{D}_{x-} can be multiplied to get \mathbf{D}_{xx} :

$$\mathbf{D}_{xx} = \mathbf{D}_{x+}\mathbf{D}_{x-} = \frac{1}{h^2} \begin{bmatrix} \ddots & \ddots & & & \mathbf{0} \\ \ddots & -2 & 1 & & \\ & 1 & -2 & 1 & \\ & & 1 & -2 & 1 \\ & & & 1 & -2 & \ddots \\ \mathbf{0} & & & & \ddots & \ddots \end{bmatrix}. \quad (2.47)$$

Averaging operators μ_{x+} , μ_{x-} and $\mu_{x\cdot}$ are defined in a similar way:

2.4. The 1D Wave Equation

$$\mathbf{M}_{x+} = \frac{1}{2} \begin{bmatrix} \ddots & & & & & & \mathbf{0} \\ & \ddots & & & & & \\ & & 1 & & 1 & & \\ & & & 1 & & & \\ & & & & 1 & & \\ & & & & & 1 & \\ & & & & & & 1 \\ & & & & & & & \ddots \\ & & & & & & & & \ddots \\ & \mathbf{0} & & & & & & & & \ddots \end{bmatrix}$$

It is important to notice that only spatial operators are written in this matrix form and then applied to state vectors at different time steps ($n+1$, n and $n-1$).

Finally, the identity matrix is a matrix with only 1s on the diagonal and 0s elsewhere as

$$\mathbf{I} = \begin{bmatrix} \ddots & & & & & \mathbf{0} \\ & 1 & & & & \\ & & 1 & & & \\ & & & 1 & & \\ & & & & 1 & \\ \mathbf{0} & & & & & \ddots \end{bmatrix} \quad (2.48)$$

Schemes and Update Equations in Matrix Form

With these building blocks we can write Eq. (2.38) in matrix form. The values of the grid function u_l^n can be stored in a state vector according to $\mathbf{u}^n = [u_0^n, u_1^n, \dots, u_N^n]^T$ where T denotes the transpose operation. The FD scheme in (2.38) can then be written in matrix form as

$$\frac{1}{k^2} (\mathbf{u}^{n+1} - 2\mathbf{u} + \mathbf{u}^{n-1}) = c^2 \mathbf{D}_{xx} \mathbf{u}^n, \quad (2.49)$$

and rewritten to a matrix form of the update equation

$$\mathbf{u}^{n+1} = (2\mathbf{I} + c^2 k^2 \mathbf{D}_{xx}) \mathbf{u}^n - \mathbf{u}^{n-1}. \quad (2.50)$$

The identity matrix is necessary here for correct matrix addition.

2.4.5 System of Linear Equations

A number of unknowns described by the same number of equations can be solved using a

2.5 Energy Analysis

Debugging physical models.

2.5.1 Mathematical tools

Continuous-time

For two functions $f(x)$ and $g(x)$ and $x \in \mathcal{D}$ their l_2 inner product along with the l_2 norm is defined as

$$\langle f, g \rangle_{\mathcal{D}} = \int_{\mathcal{D}} f g dx \quad \text{and} \quad \|f\|_{\mathcal{D}} = \sqrt{\langle f, f \rangle_{\mathcal{D}}} \quad (2.51)$$

Discrete-time

Inner product of any time series f^n and g^n and the discrete counterpart to (2.51) is

$$\langle f^n, g^n \rangle_{\mathcal{D}} = \sum_{l \in \mathcal{D}} h f_l^n g_l^n \quad (2.52)$$

where the multiplication by h is the discrete counterpart of dx the continuous definition.

Product Identities

Some useful identities used in this work are

$$(\delta_t \cdot u_l^n)(\delta_{tt} u_l^n) = \delta_{t+} \left(\frac{1}{2} (\delta_{t-} u_l^n)^2 \right), \quad (2.53a)$$

$$(\delta_t \cdot u_l^n) u_l^n = \delta_{t+} \left(\frac{1}{2} u_l^n e_{t-} u_l^n \right), \quad (2.53b)$$

$$(\delta_{t+} u_l^n)(\mu_{t+} u_l^n) = \delta_{t+} \left(\frac{1}{2} (u_l^n)^2 \right), \quad (2.53c)$$

$$(\delta_t \cdot u_l^n)(\mu_t \cdot u_l^n) = \delta_t \cdot \left(\frac{1}{2} (u_l^n)^2 \right). \quad (2.53d)$$

Again, these can be used for spatial derivatives as well by substituting the 't' subscripts for 'x'. Also to

When an operator is applied to a product of two grid functions, the discrete counter part of the product rule needs to be used according to

$$\delta_{t+}(u_l^n w_l^n) = (\delta_{t+} u_l^n)(\mu_{t+} w_l^n) + (\mu_{t+} u_l^n)(\delta_{t+} w_l^n). \quad (2.54)$$

2.6 von Neumann Analysis

Much literature gives the stability condition using an "it can be shown that" argument (fx. [2]). Here, I would like to take the opportunity to

Finding stability conditions for models

Sin identity:

$$\sin(x) = \frac{e^{jx} - e^{-jx}}{2j} \Rightarrow \sin^2(x) = \frac{e^{j2x} - 2e^{jx-jx} + e^{-j2x}}{-4} = \frac{e^{j2x} + e^{-j2x}}{-4} + \frac{1}{2}. \quad (2.55)$$

Cos identity:

$$\cos(x) = \frac{e^{jx} + e^{-jx}}{2} \Rightarrow \cos^2(x) = \frac{e^{j2x} + 2e^{jx-jx} + e^{-j2x}}{4} = \frac{e^{j2x} + e^{-j2x}}{4} + \frac{1}{2}. \quad (2.56)$$

One can analyse a FD scheme by

$$u_l^n = z^n e^{jl\beta h} \quad (2.57)$$

check 'a' or 'an' FD scheme

where β is a real wavenumber. Important to remember is that without a shift in space (fx. $l + 1$) or time (fx. $n - 1$) $l = 0$ or $n = 0$ respectively:

$$u_l^n = z^0 e^{j0\beta h} = 1 \quad (2.58a)$$

$$u_{l+1}^n = z^0 e^{j1\beta h} = e^{j\beta h} \quad (2.58b)$$

$$u_{l-1}^n = z^0 e^{j(-1)\beta h} = e^{-j\beta h} \quad (2.58c)$$

$$u_{l+2}^n = z^0 e^{j2\beta h} = e^{j2\beta h} \quad (2.58d)$$

$$u_{l-2}^n = z^0 e^{j(-2)\beta h} = e^{-j2\beta h} \quad (2.58e)$$

$$u_l^{n+1} = z^1 e^{j0\beta h} = z \quad (2.58f)$$

$$u_l^{n-1} = z^{-1} e^{j0\beta h} = z^{-1} \quad (2.58g)$$

Talk about solution of

2.7 Modal Analysis

Modes are the resonant frequencies of a system. The amount of modes that a discrete system contains depends on the amount of moving points. A

mass-spring system thus has one resonating mode, but a FD scheme of the 1D wave equation with $N = 30$ and Dirichlet boundary conditions will have 29 modes. This section will show how to obtain the modes of an FD scheme implementing the 1D wave equation.

We start by using the the matrix form of FD scheme (2.38) from Eq. (2.49)

$$\frac{1}{k^2} (\mathbf{u}^{n+1} - 2\mathbf{u}^n + \mathbf{u}^{n-1}) = c^2 \mathbf{D}_{xx} \mathbf{u}.$$

more explanation

Following [3] we assume a solution of the form $\mathbf{u} = \phi z^n$. Substituting this into Eq. (2.49) yields the characteristic equation

$$(z - 2 + z^{-1})\phi = c^2 k^2 \mathbf{D}_{xx} \phi. \quad (2.59)$$

This is an eigenvalue problem where the p 'th solution is defined as

$$\begin{aligned} z_p - 2 + z_p^{-1} &= c^2 k^2 \text{eig}_p(\mathbf{D}_{xx}) \\ z_p + (-2 - c^2 k^2 \text{eig}_p(\mathbf{D}_{xx})) + z_p^{-1} &= 0 \end{aligned} \quad (2.60)$$

where $\text{eig}_p(\cdot)$ denoting the p th eigenvalue of ' \cdot '. If the CFL condition for the scheme is satisfied, the roots will lie on the unit circle. Furthermore we can substitute a test solution $z_p = e^{j\omega_p k}$ solve for the eigenfrequencies:

$$\begin{aligned} e^{j\omega_p k} + e^{-j\omega_p k} - 2 - c^2 k^2 \text{eig}_p(\mathbf{D}_{xx}) &= 0 \\ \frac{e^{j\omega_p k} + e^{-j\omega_p k}}{-4} + \frac{1}{2} + \frac{c^2 k^2}{4} \text{eig}_p(\mathbf{D}_{xx}) &= 0 \end{aligned}$$

Then using Eq. (2.55) we get

$$\begin{aligned} \sin^2(\omega_p k/2) + c^2 k^2 \text{eig}_p(\mathbf{D}_{xx}) &= 0 \\ \sin(\omega_p k/2) &= ck \sqrt{-\text{eig}_p(\mathbf{D}_{xx})} \\ \omega_p &= \frac{2}{k} \sin^{-1} \left(ck \sqrt{-\text{eig}_p(\mathbf{D}_{xx})} \right) \end{aligned} \quad (2.61)$$

which is Eq. (6.53) in [3].

2.8 Dispersion analysis

Part II

Resonators

Resonators

Though the physical models described in the previous part are also considered resonators, they are *ideal* cases. In other words, you would not be able to find these “in the wild” as they do not include effects such as losses or dispersion in the case of the 1D wave equation.

Scaling

Scaling, or non-dimensionalisation can be useful to reduce the parameter space

Domain $x \in [0, L]$ is scaled to $x' = x/L$ such that $x' \in [0, 1]$.

The 1D wave equation in (2.36) can be rewritten to

$$\partial_t^2 u = \gamma^2 \partial_{x'}^2 u \quad (2.62)$$

where scaled wavespeed $\gamma = c/L$ has units of frequency.

Although this parameter reduction might be useful for resonators in isolation, when they are connected

Moreover, for the parameters to make

As, later on, different resonators in isolation will be connected, the overview is better kept when all parameters are written out

- Bars and Stiff Strings
- 2D Models
- Brass

Chapter 3

Stiff string

Stiff string and stuff Used in many of the publications in Part IX VI

3.1 Continuous time

Consider the transverse displacement of a lossless stiff string of length L described by $u = u(x, t)$ defined for $x \in \mathcal{D}$ with domain $\mathcal{D} = [0, L]$ and time $t \geq 0$. The PDE describing its motion is

$$\rho A \partial_t^2 u = T \partial_x^2 u - EI \partial_x^4 u \quad (3.1)$$

parameterised by material density ρ (in kg/m^3), cross-sectional area $A = \pi r^2$ (in m^2), radius r (in m) tension T (in N), Young's modulus E (in Pa) and area moment of inertia $I = \pi r^4/4$ (in m^4). If either E or I is 0, Eq (3.1) reduces to the 1D wave equation in (2.36) where $c = \sqrt{T/\rho A}$. If instead $T = 0$, Eq. (3.1) reduces to the *ideal bar* equation.

should I even include the lossless one? It's just so that we can slowly build up to the damped model...

Dispersion Analysis

The 4th-order spatial derivative models *frequency dispersion*, a phenomenon that causes different frequencies to travel at different speeds. As opposed to the undesired numerical dispersion

3.1.1 Adding Losses

Before moving on to the discretisation of Eq. (3.1), losses can be added to the system. This is done by simply adding terms to (3.1) according to

$$\rho A \partial_t^2 u = T \partial_x^2 u - EI \partial_x^4 u - 2\sigma_0 \rho A \partial_t u + 2\sigma_1 \rho A \partial_t \partial_x^2 u \quad (3.2)$$

First appeared in [1]

where the loss coefficients σ_0 (in s^{-1}) and σ_1 (in m^2/s) describe the frequency dependent and frequency independent losses respectively.

A more compact way to write Eq. (3.2), and as is also found often in the literature [3] is to divide both sides by ρA to get

$$\partial_t^2 u = c^2 \partial_x^2 u - \kappa^2 \partial_x^4 u - 2\sigma_0 \partial_t u + 2\sigma_1 \partial_t \partial_x^2 u \quad (3.3)$$

where $c = \sqrt{T/\rho A}$ is the wave speed (in m/s) as in the 1D wave equation in (2.36) and $\kappa = \sqrt{EI/\rho A}$ is a stiffness coefficient (in m^2/s).

Intuition

Although Eq. (3.2) might look daunting at first, the principle of Newton's second law remains the same.

Something about the 4th spatial derivative and the loss terms here...

Boundary Conditions

The boundary conditions found in (2.37) can be extended to

$$u = \partial_x u = 0 \quad (\text{clamped}) \quad (3.4a)$$

$$u = \partial_x^2 u = 0 \quad (\text{simply supported}) \quad (3.4b)$$

$$\partial_x^2 u = \partial_x^3 u = 0 \quad (\text{free}) \quad (3.4c)$$

3.2 Discrete Time

Equation (3.2) can be discretised as

$$\rho A \delta_{tt} u_l^n = T \delta_{xx} u_l^n - EI \delta_{xxxx} u_l^n - 2\sigma_0 \rho A \delta_t u_l^n + 2\sigma_1 \rho A \delta_t \delta_{xx} u_l^n \quad (3.5)$$

The δ_{xxxx} operator is the the second-order spatial difference in Eq. (2.9) applied to itself.

$$\delta_{xxxx} = \delta_{xx} \delta_{xx} = \frac{1}{h^4} (e_{x+}^2 - 4e_{x+} + 6 - 4e_{x-} + e_{x-}^2) \quad (3.6)$$

3.2.1 Combining operators

Operators can be combined by simply multiplying their definitions. Recalling the definitions for δ_{t-} in Eq. (2.4b) and δ_{xx} Eq. (2.9) their combination results in

$$\begin{aligned} \delta_{t-} \delta_{xx} &= \frac{1}{k} (1 - e_{t-}) \frac{1}{h^2} (e_{x+} - 2 + e_{x-}), \\ &= \frac{1}{kh^2} (e_{x+} - 2 + e_{x-} - e_{t-} (e_{x+} - 2 + e_{x-})). \end{aligned}$$

3.3. Modal analysis

A multiplication of two (different) shift operators applied to a grid function simply means to apply each shift individually. The $\delta_{t-}\delta_{xx}$ operator applied to u_l^n thus yields

$$\delta_{t-}\delta_{xx}u_l^n = \frac{1}{hk^2} (u_{l+1}^n - 2u_l^n + u_{l-1}^n - u_{l+1}^{n-1} + 2u_l^{n-1} - u_{l-1}^{n-1}). \quad (3.7)$$

3.3 Modal analysis

To perform a modal analysis on the FD scheme of the damped stiff string in (3.5)

The matrix form of the δ_{xxxx} operator in (3.6) with simply supported boundary conditions can be obtained by multiplying two \mathbf{D}_{xx} matrices according to

$$\mathbf{D}_{xx}\mathbf{D}_{xx} = \mathbf{D}_{xxxx} = \frac{1}{h^4} \begin{bmatrix} 5 & -4 & 1 & & & \mathbf{0} \\ -4 & 6 & \ddots & \ddots & & \\ 1 & \ddots & \ddots & -4 & 1 & \\ & \ddots & -4 & 6 & -4 & \ddots \\ & & 1 & -4 & \ddots & \ddots & 1 \\ & & & \ddots & \ddots & 6 & -4 \\ \mathbf{0} & & & & 1 & -4 & 5 \end{bmatrix}. \quad (3.8)$$

Chapter 5

2D Systems

In this work, it is mainly used to model a simplified body in papers...

State variable $u = u(x, y, t)$ where $t \geq 0$ and $(x, y) \in \mathcal{D}$ where \mathcal{D} is 2-dimensional. The state variable can then be discretised according to $u(x, y, t) \approx u_{l,m}^n$ with space $x = lh$ and $y = mh$ and time $t = nk$ and $k = 1/f_s$. For simplicity the grid spacing in both the x and y directions are set to be the same but could be different.

In continuous time the operators:

$$\Delta = \partial_x^2 + \partial_y^2 \quad (5.1)$$

The same shift operators as defined in Chapter 2 can be applied to grid function $u_{l,m}^n$. Additional ones are

$$e_{y+} u_{l,m}^n = u_{l,m+1}^n, \quad \text{and} \quad e_{y-} u_{l,m}^n = u_{l,m-1}^n. \quad (5.2)$$

5.1 2D Wave Equation

The 2D wave equation be used to model an ideal membrane such as done in

$$\partial_t^2 u = c^2 \Delta u \quad (5.3)$$

where $c = \sqrt{T/\rho H}$ is the wavespeed (in m/s) T is the tension per unit length applied to the boundary (in N/m), material density

check whether this is right..

5.2 Thin plate

Used in [A], [B], [D] and [E] biharmonic operator, Laplacian in (??) applied to itself.

$$\rho H \partial_t^2 u = -D \Delta \Delta u \quad (5.4)$$

where $D = EH^3/12(1 - \nu^2)$

5.3 Stiff membrane

Combination between Eqs. (5.5) and (5.4)

$$\rho H \partial_t^2 u = T \Delta u \quad (5.5)$$

7.1.1 Mass-spring Systems Revisited: Adding Damping

Damping can be added to Eq. (2.27)

$$M\ddot{u} = -Ku - R\dot{u} \quad (7.1)$$

with damping coefficient R (in kg/s). To this system we can add an external force:

$$M\ddot{u} = -Ku - R\dot{u} + F \quad (7.2)$$

where

7.2 The Bow

The bow...

Helmholtz motion..

See fx. <https://www.youtube.com/watch?v=6JeyiM0YNo4>

Characteristic triangular motion (wave shapes?)

7.2.1 Static Friction Models

In static bow-string-interaction models, the friction force is defined as a function of the relative velocity between the bow and the string only. The first mathematical description of friction was proposed by Coulomb in 1773 [?]

to which static friction, or *stiction*, was added by Morin in 1833 [?] and viscous friction, or velocity-dependent friction, by Reynolds in 1886 [?]. In 1902, Stribeck found a smooth transition between the static and the coulomb part of the friction curve now referred to as the Stribeck effect [?]. The latter is still the standard for static friction models today.

7.2.2 Dynamic Friction Models

As opposed to less complex bow models, such as the hyperbolic [source] and exponential [source] models, the elasto-plastic bow model assumes that the friction between the bow and the string is caused by a large quantity of bristles, each of which contributes to the total amount of friction.

Lip-reed model

7.3.1 Coupling to Tube

Part IV

Interactions

The models described in part II already sound quite convincing on their own. However, these are just individual components that can be combined to approximate a fully functional (virtual) instrument. The following chapters will describe different ways of interaction between individual systems. Chapter 8 describes ways to connect different systems and Chapter 9 describes collision interactions between models.

ε

Newtons third law (action reaction)

Subscripts are needed

Somewhere in this Chapter have a section about fretting and how to generate different pitches using only one string

Interpolation and spreading operators

Using $l_c = \lfloor x_c/h \rfloor$ and $\alpha_c = x_c/h - l_c$ is the fractional part the location of interest.

$$I_0(x_c) = \begin{cases} 1, & \text{if } l = l_c, \\ 0, & \text{otherwise} \end{cases} \quad (7.3)$$

$$I_1(x_c) = \begin{cases} (1 - \alpha_c), & \text{if } l = l_c \\ \alpha_c, & \text{if } l = l_c + 1 \\ 0 & \text{otherwise} \end{cases} \quad (7.4)$$

$$I_3(x_c) = \begin{cases} \dots \end{cases} \quad (7.5)$$

The following identity is very useful when solving interactions between components:

$$\langle f, J_p(x_c) \rangle_{\mathcal{D}} = I_p(x_c) f \quad (7.6)$$

Chapter 8

Connections

Something about connections

Pointlike $\delta(x - x_c)$ or distributed E_c

8.1 Rigid connection

The simplest connection is Forces should be equal and opposite.

If component a is located ‘above’ component b , and their relative displacement is defined as $\eta = a - b$, then a positive η is going to have a negative effect on a and a positive effect on b and vice-versa. This is important for the signs when adding the force terms to the schemes.

8.2 Spring-like connections

8.2.1 Connection with rigid barrier (scaled)

Consider the (scaled) 1D wave equation with an additional force term F^n

$$\delta_{tt}u_l^n = \gamma^2 \delta_{xx}u_l^n + J(x_c)F^n \quad (8.1)$$

where

$$F^n = -\omega_0^2 \mu_t \cdot \eta^n - \omega_1^4 (\eta^n)^2 \mu_t \cdot \eta^n - 2\sigma_{\times} \delta_t \cdot \eta^n \quad (8.2)$$

and

$$\eta^n = I(x_c)u_l^n. \quad (8.3)$$

To obtain F^n , an inner product of scheme (8.1) needs to be taken with $J(x_c)$ over domain \mathcal{D} which, using identity (7.6) yields

$$\delta_{tt}I(x_c)u_l^n = \gamma^2 I(x_c)\delta_{xx}u_l^n + \underbrace{I(x_c)J(x_c)}_{\|J(x_c)\|_{\mathcal{D}}^2} F^n. \quad (8.4)$$

As u is connected to a rigid barrier according to (8.3), a shortcut can be taken and Eqs. (8.2) and (8.3) can be directly substituted into Eq. (8.4) to get

$$\delta_{tt}\eta^n = \gamma^2 I(x_c) \delta_{xx} u_l^n + \|J(x_c)\|_{\mathcal{D}}^2 \left(-\omega_0^2 \mu_t \cdot \eta^n - \omega_1^4 (\eta^n)^2 \mu_t \cdot \eta^n - 2\sigma_{\times} \delta_t \cdot \eta^n \right). \quad (8.5)$$

and solved for η^{n+1} :

$$\begin{aligned} & \left(1 + \|J(x_c)\|_{\mathcal{D}}^2 k^2 [\omega_0^2/2 + \omega_1^4 (\eta^n)^2/2 + \sigma_{\times}/k] \right) \eta^{n+1} \\ &= 2\eta^n - \left(1 + \|J(x_c)\|_{\mathcal{D}}^2 k^2 [\omega_0^2/2 + \omega_1^4 (\eta^n)^2/2 - \sigma_{\times}/k] \right) \eta^{n-1} \\ &+ \gamma^2 k^2 I(x_c) \delta_{xx} u_l^n \end{aligned} \quad (8.6)$$

This can then be used to calculate F^n in (8.2) and can in turn be used to calculate u_l^{n+1} in (8.1).

8.2.2 String-plate connection

In this example, let's consider a string connected to a plate using a nonlinear damped spring. This could be interpreted as a simplified form of how guitar string would be connected to the body.

Continuous

The systems in isolation are as in (3.2) and (5.4), but with an added force term:

$$\partial_t^2 u = c^2 \partial_x^2 u - \kappa_s^2 \partial_x^4 u - 2\sigma_{0,s} \partial_t u + 2\sigma_{1,s} \partial_t \partial_x^2 u - \delta(x - x_c) \frac{f}{\rho_s A} \quad (8.7a)$$

$$\partial_t^2 w = -\kappa_p^2 \Delta \Delta w - 2\sigma_{0,p} \partial_t w + 2\sigma_{1,p} \partial_t \partial_x^2 w + \delta(x - x_c, y - y_c) \frac{f}{\rho_p H} \quad (8.7b)$$

where

$$f = f(t) = K_1 \eta + K_3 \eta^3 + R \dot{\eta} \quad (8.8)$$

and

$$\eta = \eta(t) = u(x_c, t) - w(x_c, y_c, t) \quad (8.9)$$

Discrete

System (8.7) can then be discretised as

$$\delta_{tt} u_l^n = c^2 \delta_{xx} u_l^n - \kappa_s^2 \delta_{xxxx} u_l^n - 2\sigma_{0,s} \delta_t \cdot u_l^n + 2\sigma_{1,s} \delta_{t-} \delta_{xx} u_l^n - J_s(x_c) \frac{f^n}{\rho_s A}, \quad (8.10)$$

$$\delta_{tt} w_l^n = -\kappa_p^2 \delta_{\Delta} \delta_{\Delta} w_l^n - 2\sigma_{0,p} \delta_t \cdot w_l^n + 2\sigma_{1,p} \delta_{t-} \delta_{xx} w_l^n + J_p(x_c, y_c) \frac{f^n}{\rho_p H}, \quad (8.11)$$

8.2. Spring-like connections

where

$$f^n = K_1 \mu_{tt} \eta^n + K_3 (\eta^n)^2 \mu_t \eta^n + R \delta_t \eta^n, \quad (8.12)$$

and

$$\eta^n = I(x_c) u_l^n - I(x_c, y_c) w_l^n. \quad (8.13)$$

Expansion

System (8.10) can be expanded at the connection location x_c by taking an inner product of the schemes with their respective spreading operators.

8.2.3 Solving for f

8.2.4 Non-dimensional

The scaled system can be written as:

$$\partial_t^2 u = \gamma^2 \partial_x^2 u - \kappa_s^2 \partial_x^4 u - 2\sigma_{0,s} \partial_t u + 2\sigma_{1,s} \partial_t \partial_x^2 u - \delta(x - x_c) F \quad (8.14)$$

$$\partial_t w = -\kappa_p^2 \Delta \Delta w - 2\sigma_{0,p} \partial_t w + 2\sigma_{1,p} \partial_t \partial_x^2 w + \delta(x - x_c, y - y_c) F \quad (8.15)$$

where

$$F = F(t) = \omega_1^2 \eta + \omega_3^4 \eta^3 + \sigma_c \dot{\eta} \quad (8.16)$$

and

$$\eta = \eta(t) = u(x_c, t) - w(x_c, y_c, t) \quad (8.17)$$

$$I(x_c) \delta_{tt} u_l^n = c^2 (I(x_c) \delta_{xx} u_l^n) + I(x_c) J(x_c) F \quad (8.18)$$

Part V

Dynamic Grids

Chapter 10

Dynamic Grids

Often in math, you should view the definition not as a starting point, but as a target. Contrary to the structure of textbooks, mathematicians do not start by making definitions and then listing a lot of theorems, and proving them, and showing some examples. The process of discovering math typically goes the other way around. They start by chewing on specific problems, and then generalising those problems, then coming up with constructs that might be helpful in those general cases, and only then you write down a new definition (or extend an old one). - Grant Sanderson (AKA 3Blue1Brown) <https://youtu.be/O85OWBJ2ayo?t=359>

10.1 Background and Motivation

Simulating musical instruments using physical modelling – as mentioned in Part I – allows for manipulations of the instrument that are impossible in the physical world. Examples of this are changes in material density or stiffness, cross-sectional area (1D), thickness (2D) and size. Apart from being potentially sonically interesting, there are examples in the physical world where certain aspects of the instrument are manipulated in real-time.

check if is still true

Tension in a string is changed when tuning it

Some artists even use this in their performances [9, 11]

The hammered dulcimer is another example where the strings are tensioned over a bridge where one can play the string at one side of the bridge, while pushing down on the same string on the other side [8].

1D:

- Trombone
- Slide whistle
- Guitar strings

- Fretting finger pitch bend
- Above the nut [11]
- Tuning pegs directly [9]
- Hammered dulcimer [8]
- Erhu?

2D:

- Timpani
- Bodhrán: <https://youtu.be/b9HyB5yNS1A?t=146>
- Talking drum (hourglass drum): <https://youtu.be/B4oQJZ2TEVI?t=9>
- Flex-a-tone (could also be 1D tbh.): <https://www.youtube.com/watch?v=HEW1aG8XJQ>

A more relevant example is that of the trombone, where the size of the instrument is changed in order to play different pitches. Modelling this using FDTD methods would require

In his thesis, Harrison points out that in order to model the trombone, grid points need to be introduced

10.2 Method

Iterations have been:

- Interpolated boundary conditions
- Linear interpolation

In this appendix, some iterations done over the course of this project will be shown in more detail. In the following, the 1D wave equation with a wave speed of $c = 1470$ m/s, a length of $L = 1$ m, Dirichlet boundary conditions and a sample rate of $f_s = 44100$ Hz is considered, and – through Eq. (??) – satisfies the CFL condition with equality. These values result in $N = 30$, or a

These sections are taken from the JASA appendix

grid of 31 points including the boundaries. Then, the wave speed is decreased to $c \approx 1422.6$ m/s, i.e., the wave speed that results in $N = 31$ and satisfies the stability condition with equality again.

10.2.1 Full-Grid Interpolation

One way to go from one grid to another is performing a full-grid interpolation [3, Chap. 5]. If the number of points changes according to Eq. (??), i.e., if $N^n \neq N^{n-1}$ the full state of the system ($u_l^n, u_l^{n-1} \forall l$) can be interpolated to the new state. See Figure 10.1.

Fig. 10.1: Upsampling u (with an arbitrary state) using (linear) full-grid interpolation with $N^{n-1} = 30$ and $N^n = 31$. The horizontal axis is normalised with respect to N^n .

An issue that arises using this method is that the Courant number λ will slightly deviate from the CFL condition as c changes. Using Eq. (??) with L/ck approaching 31 (from below), the minimum value of $\lambda \approx 30/31 \approx 0.9677$. This, employing Eq. (??), has a maximum frequency output of $f_{\max} \approx 18,475$ Hz. The Courant number will deviate more for higher values of c and thus lower values for N – for instance, if N approaches 11 (from below), $\lambda \approx 10/11 \approx 0.9091$ and $f_{\max} \approx 16,018$ Hz.

Another problem with full-grid interpolation, is that it has a low-passing effect on the system state, and thus on the output sound. Furthermore, this state-interpolation causes artefacts or ‘clicks’ in the output sound as the method causes sudden variations in the states.

All the aforementioned issues could be solved by using a (much) higher sample rate and thus more grid points, but this would render this method impossible to work in real time.

10.2.2 Adding and removing Points at the Boundary

To solve the issues exhibited by a full-grid interpolation, points can be added and removed at a single location and leave most points unaffected by the parameter changes. A good candidate for a location to do this is at a fixed

Fig. 10.2: The simply supported boundary condition: both the state and the curvature at the boundary – at $l = 0$ – should be 0.

(Dirichlet) boundary. The state u at this location is always 0 so points can be added smoothly.

As c decreases, h can be calculated according to Eq. (??) and decreases as well.

This has a physical analogy with tuning a guitar string. Material enters and exits the neck (playable part of the string) at the nut, which in discrete time means grid points appearing and disappearing at one boundary.

To yield smooth changes between grid configurations, an interpolated boundary has been developed, the possibility of which has been briefly mentioned in [3, p. 145]. The Dirichlet condition in Eq. (2.37a) can be extended to be the simply supported boundary condition:

$$u(x, t) = \frac{\partial^2}{\partial x^2} u(x, t) = 0 \quad \text{where} \quad x = 0, L, \quad (10.1)$$

or, when discretised,

$$u_l^n = \delta_{xx} u_l^n = 0, \quad \text{where} \quad l = 0, N. \quad (10.2)$$

This means that on top of that the state of the boundary should be 0, the curvature around it should also be 0. One can again solve for the virtual grid points at the boundary locations, yielding

$$u_{-1}^n = -u_1^n \quad \text{and} \quad u_{N+1}^n = -u_{N-1}^n. \quad (10.3)$$

This is visualised in Figure 10.2.

10.2. Method

Fig. 10.3: The grid changing over time

If the flooring operation in Eq. (??) is removed this introduces a fractional number of grid points.

The by-product of using a fractional N this is that the CFL condition in (2.39) can now always be satisfied with equality no matter what the wave speed is.

An issue with this method is that removing points is much harder than adding.

their interactions change through a change in the grid spacing and wave speed. This interaction, though, is defined by λ which

10.2.3 Cubic interpolation

10.2.4 Sinc interpolation

10.2.5 Displacement correction

The displacement correction can be interpreted as a spring force pulling u_M^n and w_0^n to the average displacement.

$$\begin{aligned} u_M^{n+1} &= 2u_M^n + \lambda^2(u_{M-1}^n - 2u_M^n + u_{M+1}^n) - K \left(u_M^n - \frac{u_M^n + w_0^n}{2} \right) \\ w_0^{n+1} &= 2u_M^n + \lambda^2(w_{-1}^n - 2w_0^n + w_1^n) - K \left(w_0^n - \frac{u_M^n + w_0^n}{2} \right) \end{aligned} \quad (10.4)$$

$$\begin{aligned} u_M^{n+1} &= 2u_M^n + \lambda^2(u_{M-1}^n - 2u_M^n + u_{M+1}^n) + \frac{K}{2}(w_0^n - u_M^n) \\ w_0^{n+1} &= 2u_M^n + \lambda^2(w_{-1}^n - 2w_0^n + w_1^n) - \frac{K}{2}(w_0^n - u_M^n) \end{aligned} \quad (10.5)$$

with $K = K(\alpha)$

$$K = (1 - \alpha)^\epsilon. \quad (10.6)$$

10.3 Analysis and Experiments

... where to add and remove points

Using the whole range, we can still add/remove points at the sides.

10.4 Discussion and Conclusion

Part VI

Real-Time Implementation and Control

Real-Time Implementation and Control

It's all fun and dandy with all these physical models, but what use are they if you can't control them in real time?!

Chapter 11

Real-Time Implementation

JUCE Give overall structure of code

Implementation of the physical models using FDTD methods

As mentioned in Chapter 1, FDTD methods are used for high-quality and accurate simulations, rather than for real-time applications. This is due to their lack of simplifications.

Usually, `MATLAB` is used for simulating

Here, an interactive application is considered real-time when

Control of the application generates or manipulates audio with no noticeable latency.

Also the application needs to be controlled continuously

Helps to (informally) evaluate the models by interacting with it in a natural way (rather than static parameters)

11.1 `MATLAB` vs. `C++`

It is usually a good idea to prototype a physical modelling application in `MATLAB` for several reasons:

- Easier to debug
 - Plotting functionality
 - No need for memory handling
- Instability due to programming errors

11.1.1 Speed

Here is where the power of `C++`

11.1.2 Syntax

Indexing in Matlab is 1-based, meaning that the index of a vector starts at 1. If u is a vector with 10 elements, the first element is retrieved as $u(1)$ and the last as $u(10)$. C++, on the other hand, is 0-based and retrieving the first and last element of a size-10 vector happens through $u[0]$ and $u[9]$ respectively.

11.2 Do's and don'ts in Real-Time FD schemes

Some of the things I learned (the hard way)...

- Create a limiter
- Structure your application into classes
- Use pointer switches
- Comment your code (hehe)

Create a limiter

Programming errors happen. To save your speakers, headphones or – most importantly – your ears, create a limiter.

```
double limit (double val)
{
    if (val < -1)
    {
        val = -1;
        return val;
    }
    else if (val > 1)
    {
        val = 1;
        return val;
    }
    return val;
}
```

```
1 for i = 0:lengthSound
2     uNext = ...
3 end
```

Use pointer switches

One of the most important things in working with FD schemes for real-time audio applications is to

The maximum number of copy-operations this takes is $2(N + 1)$ if the boundaries also need updated in the case of free or Neumann boundary conditions. For a string with simply supported or clamped boundary conditions this can be reduced to $2N$ or $2(N - 1)$ respectively, but does not make a big difference in computational time.

A pointer switch, however, only needs 4 copy-operations per iteration as shown in Algorithm 11.1

```

1 for n = 1:lengthSound
2     ...
3     uPrev = u;
4     u = uNext;
5 end

```

In C++ this is done using

```

double updateStates()
{
    double* uTmp = u[2];
    u[2] = u[1];
    u[1] = u[0];
    u[0] = uTmp;
}

```

Algorithm 11.1: Implementation of a pointer switch also shown in Figure 11.1b. A temporary pointer is assigned to where the u^{n-1} pointer is currently pointing at to be able to assign that location in memory to the u^{n+1} pointer in the end.

Grouping terms and Precalculating coefficients

Generally in implementations of FD schemes the most computationally expensive part of the algorithm is the calculation of the scheme itself. This is due to the rate at which it needs to be updated which usually is 44100 Hz. Graphics can be updated at rates orders of magnitude lower than the audio (say 10-20 Hz) and still be considered smooth enough.

The undamped stiff string FD scheme

$$\delta_{tt}u_l^n = c^2\delta_{xx}u_l^n - \kappa^2\delta_{xxx}u_l^n, \quad (11.1)$$

can be expanded to an update equation as

$$\begin{aligned} u_l^{n+1} = & 2u_l^n - u_l^{n-1} + \lambda^2 (u_{l+1}^n - 2u_l^n + u_{l-1}^n) \\ & - \mu^2 (u_{l+2}^n - 4u_{l+1}^n + 6u_l^n - 4u_{l-1}^n + u_{l-2}^n) \end{aligned} \quad (11.2)$$

where $\lambda = ck/h$ and $\mu = \kappa k/h^2$.

For implementation purposes there is a better way to write this scheme that reduces the amount of computations. This is done by collecting the terms based on the grid function and pre-calculating the coefficients multiplied onto these. As the schemes are spatially symmetric, “neighbouring points” relative to u_l^n can also be grouped to get

$$u_l^{n+1} = \underbrace{(2 - 2\lambda^2 - 6\mu^2)}_{B1} u_l^n + \underbrace{(\lambda^2 + 4\mu^2)}_{B2} (u_{l+1}^n + u_{l-1}^n) - \underbrace{\mu^2}_{B3} (u_{l+2}^n + u_{l-2}^n) - \underbrace{u_l^{n-1}}_{C1}. \quad (11.3)$$

These coefficients can then be pre-calculated and do not have to be

```

//// Constructor ////
B1 = 2.0 - 2.0 * lambdaSq - 6.0 * muSq; // u_l^n
B2 = lambdaSq + 4.0 * muSq;           // u_{l+1}^n
B3 = -muSq;                          // u_{l+2}^n
C1 = -1.0;                           // u_l^{n-1}

//// Function where scheme is calculated ////
for (int l = 2; l < N-1; ++l) // clamped boundaries
{
    u[0][l] = B1 * u[1][l]
              + B2 * (u[1][l+1] + u[1][l-1])
              + B3 * (u[1][l+2] + u[1][l-2])
              + C1 * u[2][l];
}

```

Algorithm 11.2: Precalculation

11.3 Graphics

11.3. Graphics

```
void Simple1DWave::paint (juce::Graphics& g)
{
    // clear the background
    g.fillAll (getLookAndFeel().findColour
        (juce::ResizableWindow::backgroundColourId));

    Path stringState = visualiseState (g, 100);

    // choose your favourite colour
    g.setColour (Colours::cyan);

    // visualScaling depends on your excitation
    g.strokePath (visualiseState (g, 100), PathStrokeType(2.0f));
}

Path Simple1DWave::visualiseState (Graphics& g, double visualScaling)
{
    // String-boundaries are in the vertical middle of the component
    double stringBoundaries = getHeight() / 2.0;

    // initialise path
    Path stringPath;

    // start path
    stringPath.startNewSubPath (0, -u[1][0] * visualScaling +
        stringBoundaries);

    double spacing = getWidth() / static_cast<double>(N);
    double x = spacing;

    for (int l = 1; l <= N; l++)
    {
        // Needs to be -u, because a positive u would visually go down
        float newY = -u[l][1] * visualScaling + stringBoundaries;
        if (isnan(x) || isinf(abs(x)) || isnan(u[l][1]) ||
            isinf(abs(u[l][1])))
            std::cout << "Wait" << std::endl;

        // if we get NAN values, make sure that we don't get an
        // exception
        if (isnan(newY))
            newY = 0;

        stringPath.lineTo (x, newY);
        x += spacing;
    }

    return stringPath;
}
```

```
void Simple1DWave::excite()
{
    //// Raised cosine excitation ////

    // width (in grid points) of the excitation
    double width = 10;
    double excitationLoc = 0.2;
    // make sure we're not going out of bounds at the left boundary
    int start = std::max (floor((N+1) * excitationLoc) - floor(width *
    0.5), 1.0);

    for (int l = 0; l < width; ++l)
    {
        // make sure we're not going out of bounds
        // at the right boundary (this does 'cut off'
        // the raised cosine)

        if (l+start > N - 1)
            break;

        u[1][l+start] += 0.5 * (1 - cos(2.0 * double_Pi * l /
        (width-1.0)));
        u[2][l+start] += 0.5 * (1 - cos(2.0 * double_Pi * l /
        (width-1.0)));
    }
}
```

(a) Copying values: $2(N + 1)$ operations per iteration.

(b) Pointer switch: 4 operations per iteration.

Fig. 11.1: Updating the state vectors by (a) copying all values individually, or (b) performing a pointer switch. Non-zero values are highlighted in green for clarity. The values of the red vector will be overwritten by the update of the scheme in the next iteration so these values will no longer be used.

Published in [H]

15.1 Introduction

Interesting read: <https://newt.phys.unsw.edu.au/jw/brassacoustics.html>

15.2 Physical Model

Most has been described in Chapter 4

15.2.1 Continuous

Just to save the conversation with Stefan about Webster's equation:

Using operators ∂_t and ∂_x denoting partial derivatives with respect to time t and spatial coordinate x , respectively, a system of first-order PDEs describing the wave propagation in an acoustic tube can then be written as [A]

$$\frac{S}{\rho_0 c^2} \partial_t p = -\partial_x (Sv) \quad (15.1a)$$

$$\rho_0 \partial_t v = -\partial_x p \quad (15.1b)$$

with acoustic pressure $p = p(x, t)$ (in N/m^2), particle velocity $v = v(x, t)$ (in m/s) and (circular) cross-sectional area $S(x)$ (in m^2). Furthermore, ρ_0 is the density of air (in kg/m^3) and c is the speed of sound in air (in m/s). System (15.1) can be condensed into a second-order equation in p alone, often referred to as Webster's equation [?]. Interesting! In NSS it is the acoustic potential right? Can you go from that to a second-order PDE in p ? There is a time-derivative hidden there somewhere right? (Just wondering :) Yes, the form

in p alone is the one you usually see. You get it by differentiating the first equation, giving you a \dot{v} on the RHS, and then you can substitute the second equation in...I used the velocity potential one because it has direct energy balance properties. Right. So Webster's eq. in p and Ψ are identical (will exhibit identical behaviour), except for the unit of the state variable..?yes that's right...using the velocity potential allows you to do all the energy analysis easily, in terms of physical impedances. But the scheme you get to in the end is the same, just one derivative down. Alright cool! Thanks for the explanation :) For simplicity, effects of viscothermal losses have been neglected in (15.1). For a full time domain model of such effects in an acoustic tube, see, e.g. [?].

15.2.2 Discrete

15.3 Real-Time Implementation

Unity??

15.4 Discussion

more for your info, don't think I want to include this: To combat the drift, experiments have been done involving different ways of connecting the left and right tube. One involved alternating between applying the connection to the pressures and the velocity. Here, rather than adding points to the left and right system in alternating fashion, points were added to pressures p and q and velocities v and w in an alternating fashion. Another experiment involved a "staggered" version of the connection where (fx.) for one system (either left or right), a virtual grid point of the velocity was created from known values according to (??), rather than both from pressures. This, however, showed unstable behaviour. No conclusory statements can be made about these experiments at this point. ← which is exactly why I don't want to include this section

As the geometry varies it matters a lot where points are added and removed as this might influence the way that the method is implemented. speculative section coming up The middle of the slide crook was chosen, both because it would be reasonable for the air on the tube to "go away from" or "go towards" that point as the slide is extended or contracted, and because the geometry does not vary there. Experiments with adding / removing grid points where the geometry varies have been left for future work. even more speculative.. → It could be argued that it makes more sense to add points at the ends of the inner slides as "tube material" is also added there. This would mean that the system should be split in three parts: "inner slide", "outer slide" and "rest", and would complicate things even more.

List of Symbols

The list of symbols found below contains often-used symbols in the thesis in the context that they are normally used. Depending on the context they might carry a different meaning (y being displacement of the lip-reed in Chapter 15 but the vertical spatial coordinate for 2D systems in fx. Chapter 5). Some might also be accompanied by a subscript in the main document

Symbol	Description	Unit
α	Fractional part of	
A	Cross-sectional area of string	m^2
c	Wave speed	m/s
$\frac{d^n}{dt^n}$	n^{th} order derivative with respect to t	-
∂_t^n	n^{th} order partial derivative with respect to t	-
$\delta_{t+}, \delta_{t-}, \delta_t.$	Forward, backward and centred difference in time	-
$\delta_{x+}, \delta_{x-}, \delta_x.$	Forward, backward and centred difference in space	-
$\mu_{t+}, \mu_{t-}, \mu_t.$	Forward, backward and centred average in time	-
$\mu_{x+}, \mu_{x-}, \mu_x.$	Forward, backward and centred average in space	-
E	Young's Modulus	$\text{Pa} (\text{kg}\cdot\text{m}^{-1}\cdot\text{s}^{-2})$
f	Force or frequency	N or Hz
f_s	Sample rate	Hz
F	Scaled force	depends on system

Appendix A. List of Symbols

Symbol	Description	Unit
h	Grid spacing	m
H	Membrane / Plate thickness	m
I	Area moment of inertia	m ⁴
l	Spatial index to grid function	-
L	Length	m
k	Time step ($= 1/f_s$)	s
K	Spring coefficient	N/m
κ	Stiffness coefficient	m ² /s (1D) m ⁴ ·s ⁻² (2D)
n	Sample index to grid function	-
N	Number of points string	-
\mathbb{N}^0	Set of non-negative integers	-
t	Time	s
T	Tension	N (N/m in 2D)
u	State variable	m
x	Spatial dimension (horizontal for 2D systems)	m
y	Vertical spatial dimension	m
γ	Scaled wave speed	s ⁻¹
λ	Courant number for 1D wave eq. ($= ck/h$)	-
μ	Stiffness free parameter	-
ν	Poisson's ratio	-
η	Relative displacement spring	m
ρ	Material density	kg·m ⁻³
Subscripts		
c	Connection	
p	Plate	
s	String

Papers

Paper Errata

Here, some errors in the published papers will be listed:

Real-Time Tromba [D]

- The minus sign in Eq. (28) (and thus Eqs. (31) and (35)) should be a plus sign.
- $\sigma_{1,s}$ in Eq. (21) should obviously be $\sigma_{1,p}$
- the unit of the spatial Dirac delta function δ should be m^{-1}

DigiDrum [F]

- σ_0 and σ_1 should be multiplied by ρH in order for the stability condition to hold.
- stability condition is wrong. Should be:

$$h \geq \sqrt{c^2 k^2 + 4\sigma_1 k + \sqrt{(c^2 k^2 + 4\sigma_1 k)^2 + 16\kappa^2 k^2}} \quad (1)$$

- Unit for membrane tension is N/m.

Dynamic grids [G]

- Reference in intro for ‘recently gained popularity’ should go to [4]
Note: not really an error, but should be changed before resubmission

Paper A

Real-Time Control of Large-Scale Modular Physical Models using the Sensel Morph

Silvin Willemsen, Nikolaj Andersson, Stefania Serafin
and Stefan Bilbao

The paper has been published in the
Proceedings of the 16th Sound and Music Computing (SMC) Conference, pp.
275–280, 2019.
